Collection ISO Identification of testis-specific
genes in giant panda (*Ailuropoda melanoleuca*):
characterization of a male-specific transcript

encoding an ortholog of the family member variant 3 (FMN1) and identification of four novel genes. The giant panda (*Ailuropoda melanoleuca*) is a critically endangered, slow growing, and sexually dimorphic, mammal living in very cold regions of China. Efforts have been made to preserve giant pandas, but recent studies have shown that the male giant panda lacks several common spermatogenic cell types, indicating that this species is aspermatogenic. Identification of genes that are expressed and function in germ cell development is important for the maintenance and preservation of endangered species. In this study, we identified several novel genes expressed in the testis of the giant panda, including a testis-specific gene encoding a likely ortholog of the family member variant 3 (FMN1), a gene similar to DDX3, TINY2, and LARS2, and four novel genes, all of which are expressed in the testis. The testis-specific gene

encoding a likely ortholog of FMN1, which is characterized by multiple repeated domains, was found to be exclusively expressed in the testis.

The gene product contains two domains that show homology to the FMN domains found in yeast and human FMN1. In addition, TINY2, DDX3, and LARS2 have the potential to form a complex as shown by the possible interaction of the three proteins in yeast two-hybrid studies.

The data presented here will contribute to the identification of genes involved in spermatogenesis and the maintenance of germ cells. Sergey Mikhailov (ice hockey, born 1988)

desktop publishing software Many
communications systems have been developed,
and can be used, to connect a terminal (such as a
personal computer, laptop computer, handheld
device, smart phone, or PDA) with the Internet.
Although any type of terminal can be used with
a communications system, there are different
types of communications systems that are
developed to operate with a mobile terminal
having limited communication resources. For
example, a wireless wide area network
(WWAN) can operate with a mobile terminal,
such as a cellular telephone or personal digital
assistant (PDA). WWANs can be implemented
with code division multiple access (CDMA),
time division multiple access (TDMA), Global
System for Mobile communications (GSM),
and/or WiMAX technologies. Many WWANs
include services that provide secure
communication between a mobile terminal and a

server. Secure communication is sometimes provided using a secure socket layer (SSL) protocol. SSL is commonly used for secure communication of data over the Internet. SSL is commonly implemented in products such as a Web browser, e-mail client, and XML (eXtensible Markup Language) translator. SSL can use a secret key to encrypt and decrypt data. A mobile terminal may need to establish a secure communication session to a WWAN, and to authenticate the mobile terminal to the WWAN before a secure communication session can be provided. The mobile terminal can use a user name and password to authenticate to the WWAN. Although user names and passwords can be used to authenticate a mobile terminal to a WWAN, user names and passwords can be insecure. For example, a user name can be compromised by a malicious user. A user name and password may be sent to a malicious user that can then use the user name and password to

gain access to the mobile terminal and the WWAN. Moreover, if a user name and password are used in more than one mobile terminal, the same user name and password can be used in different mobile terminals to gain access to the same WWAN. Questions and answers for the next generation Navigation We have all heard of hash wars, we have watched the major mining pools battle it out, but what are they actually doing? The concept of a hash war comes from the fact that miners have so much mining power and are so keen to compete. There are some who say that this may be harming the security of the whole network, but what is the reality f678ea9f9e
